This means you can create complex, repeatable tasks and quickly execute them with a few keystrokes. The key

to writing powerful macros is to understand the basics of VBA: variables, operators, and functions. VBA is a language that's similar to C/C++. VBA offers a wide variety of other features that can make it more versatile. This article will briefly go over the basics of VBA. For a more in-depth explanation, check out one of our other articles. VBA Basics This section will briefly go over some of the basics of VBA. Variables To write VBA code, you first have to define variables. Variables are variables that hold data, numbers, or text. The syntax to define a variable is as follows: 'variableName' '=' theValue' The variable name is written in quotation marks, while the Value is written with no quotation marks. There are two types of variables: Constant and Local. Constant variables are always available and will retain the value assigned when the script is run again. This is important, because many macros require an initial value for some variables. Constant variables are declared with the following syntax: 'Constant' 'Variable' While Local variables are temporary variables that can change when the script is run again. Local variables are declared with the following syntax: 'Local' 'Variable' Boolean Values Boolean values, also called bit fields, are just a special form of constant variables. The syntax for Boolean values is as follows: 'True' 'False' More Data Types In VBA, data can be held in a number of different data types. The 82157476af
